❷ Methodology: by Ayush Raina

Methodology

Distance Restraints and Energy Assisted Modelling

DREAM algorithm uses distance restraints obtained from NMR data to model the structure of proteins in 3 steps:
1. **Construction of Substructures:** We divide the available distance restraints data into dense fragments and model their structure first.

But why DREAM ?

- Uses divide and conquer approach which increases robustness and scalability.
- Reduces numerical instabilities because of the use of dense fragments.

But why DREAM ?

- Uses divide and conquer approach which increases robustness and scalability.

- Reduces numerical instabilities because of the use of dense fragments.

- In sequential registration, the error keeps on accumulating which is not the case in one shot registration.
Sequential vs One Shot Registration

Integrative Modelling Platform

Now we already know what is IMP. It is computationally expensive
and time consuming due Markov Chain Monte Carlo (MCMC)
sampling.

We wish to replace the computationally expensive sampling
techniques to paradigms used in DREAM:

- Orientate the structures of subunits based on experimental
  evidence which is similar to substruture computation in
  DREAM
- Register the subunits in one shot while respecting the
  experimental evidence. (an enhancement of DREAM's
  registration)

How will this happen ?

- Our substructures in this case are different kinds of proteins.
- We have cross-links data available these proteins.

Given this information, we need to do one shot registration of these proteins to model the structure of complex.

Inputs

Figure 9: Example of 2 proteins with cross-links data
Problem

Figure 10: Consider A,B as proteins and the lines as cross-links

Solution

Consider S as hypothetical framework.

Solution

Consider S as hypothetical framework. Then we can do one shot registration of A,S and B

Solution

Some Observations

1. In the hypothetical framework, we have all pairs of distances between C-alpha atoms in each protein.

Some Observations

1. In the hypothetical framework, we have all pairs of distances between C-alpha atoms in each protein.

2. For registering n proteins, only 1 hypothetical fragment is needed. So registration of $n + 1$ proteins is done.
